

## Conductor content processing and querying

Sequence diagram of calls for the 'Conductor' content processing orchestrator. This shows:

- new content processing sequence -- content acquisition in the raw store triggers ETL to normalized objects which are stored in the Content store with appropriate vector indexes constructed
- The old content removal sequence -- content older than two weeks removed from system with appropriate updates to linked objects
- processing an SQL query from a BI Tool -- query is directly to relational database layer for aggregation, and later drill down to individual records that user decides should be recorded in Check for annotation
- handling a query from a bot in Check -- newly arriving content is vectorized and any matching items are returned to show to user as context for the fact checking process
